

1. Information about the indicator	
Goal	Ensuring the availability and rational use of water resources and sanitation for all
Task	By 2030, ensure universal and equal access to safe and affordable drinking water for all
The indicator	Public access to water supply services
2. Information about the organization	
Organization	Committee on Construction and Housing and Communal Services of the Ministry of Industry and Construction of the Republic of Kazakhstan
3. Definitions and concepts	
Definition	The indicator is defined as the total number of residents with centralized water supply divided by the total number of residents in localities: 1) Public access to water supply services in cities is the proportion of the urban population with access to centralized water supply networks, as well as access to water intake pumps from the total urban population. 2) water supply services – services provided to the consumer, including water supply, to ensure safe and comfortable living conditions (stay); 3) A centralized water supply system is a complex of engineering networks and structures designed to collect, prepare, store, transport and supply drinking water to water consumers.
Basic concepts:	Access to water supply services refers to the availability of safe drinking water from uninterrupted sources.
Justification and interpretation	This indicator is widely used at the national and international levels to assess the provision of high-quality drinking water to the population of the country, and also shows the presence of problematic issues of drinking water supply. Providing the population with safe and affordable water is an important factor for human health and the economy. Everyone has the right to adequate, continuous, safe, affordable and affordable water supply for personal and household needs. It is necessary to monitor public access to water supply services in order to better understand the current state of drinking water supply in settlements by region and carry out the necessary measures to update, build, reconstruct and modernize engineering networks to ensure the quality and reliability of the services provided.
4. Data sources and collection methods	
Data sources	The source is data forms designed to collect administrative data in the field of water supply and sanitation
Data collection methods	Reports of local executive bodies of regions, cities of republican significance, the capital, cities of regional significance, cities of regional significance
Unit of measurement	Percent
Periodicity	Annually Annually until March 1, following the reporting year
5. Calculation method and other methodological considerations	
Calculation method:	The indicator is calculated as the total number of residents with

	access to water services divided by the total number of residents in localities. $D = \left(\frac{N}{M} \right) * 100, \text{ where:}$ D – public access to water supply services in towns and villages (result, source – data from the CHCS MIC RK); N – number of residents with access to water supply services in urban and rural settlements, people (source – data from LEB); M – total population in urban settlements, people (source – BNS ASPR RK data); Unit of measurement – %
Comments and restrictions:	The indicator is decomposed from the Map of Strategic Indicators until 2025: Priority. Balanced territorial development. Indicator. Public access to water supply services. Also from the Concept of Housing and Communal Infrastructure Development for 2023-2029: The target indicator. 100% of the population has access to water supply services in cities and villages.
6. Data availability and disaggregation	
Data availability and gaps:	The data is available on the website of the MIC RK.
The level of disaggregation:	City, village.
7. Comparability with international data/standards	According to the UN methodology, data on the indicator are taken from surveys of households with access to drinking water and compared with administrative data on their quality, while the MIC monitors the activities of centralized drinking water supply systems, which are a complex of interconnected water bodies and hydraulic structures combining water intake, water treatment plants, reservoirs of clean drinking water, water pipes, etc. pumping stations and networks for providing drinking water to water consumers. At the same time, this indicator characterizes the availability of access by the population to well-maintained access to drinking-quality water.
