

1. Information about the indicator	
Goal	Protection, restoration of terrestrial ecosystems and promotion of their rational use, rational forest management, combating desertification, stopping and reversing the process of land degradation and ending the process of loss
Task	By 2020, promote the implementation of rational use of all types of forests, stop deforestation, restore degraded forests and significantly expand the scale of afforestation and reforestation worldwide.
The indicator	The area of the territory covered by forest
2. Information about the organization	
Organization	Committee of Forestry And Wildlife of The Ministry Of Ecology And Natural Resources Of The Republic Of Kazakhstan
3. Definitions and concepts	
Definition	A dynamic and evolving concept that aims to support and enhance the economic, social and environmental values of all types of forests for the benefit of present and future generations
Basic concepts:	The indicator consists of five sub-indicators that measure progress in all aspects of sustainable forest management. The ecological value of forests is covered by three sub-indicators focused on the expansion of forest area, biomass in the forest area and the protection and maintenance of biological diversity, as well as natural and related cultural resources. The socio-economic value of forests is aligned with the environmental value through sustainable forest management plans. A sub-indicator is a detailed definition of the scope of forestry management, evaluating areas that are independently validated and verified for compliance with a set of national or international standards. Sub-indications of: • Change in net forest area • Terrestrial biomass reserves in forests • The proportion of forest area located in legally protected areas • The percentage of forest area for which a long-term forestry management plan has been developed • Forest area within the framework of an independent approved forestry certification system The dashboard is used to evaluate progress related to the five sub-indicators. Using the dashboard provides a clear view of the areas where progress has been made towards achieving the Sustainable Development Goals.
Justification and interpretation	The UN General Assembly definition of «sustainable forest management» contains several key aspects, in particular that sustainable forest management is a concept that changes over time and differs between countries, whose circumstances - environmental, social and economic - vary widely, and that it should always cover a wide range of forest management indicators, including economic, social and environmental values, and consider equity from the perspective of different generations
4. Data sources and collection methods	
Data sources	Statistical reporting form No. 8-LX and accounting of the forest fund for forest management materials
Data collection methods	The reports are provided by the regional territorial inspections of

	forestry and wildlife, state national nature parks, state nature reserves, state forest reserves and forestry institutions under the operation of local executive bodies.
Unit of measurement	Thousand ha/million m ³ / percentage
Periodicity	Annual
5. Calculation method and other methodological considerations	
Calculation method:	The area of the territory covered by forest: The indicator for the area of the territory covered by forest is not provided for calculation and formula. At the same time, this indicator is indicated in the explanatory note to the forest management materials, which is compiled on the basis of accounting for the forest fund of environmental protection and forestry institutions of the RSE "Kazakh Forestry Enterprise", where the summary information takes into account the percentage of forest cover of the territory from the total area of the country and may change annually depending on changes in the area of the forested territory of the state forest fund. Terrestrial biomass reserves in forests: The calculation and formula are not provided for the indicator of terrestrial biomass reserves in forests. At the same time, this indicator is related to the indicator for the stock of plantings, which is taken into account separately by species, depending on its value of at least 5 m³ per hectare for tree species and 0.1 m³ for saxaul trees, which is determined by field forestry work. This indicator is reflected in the form No. 2 of the state accounting of the forest fund. Change in net forest area: This indicator depends on the annual change in the area covered by forests to the area of the previous year. The proportion of forest area located in legally protected areas: The indicator for the share of forest area located in legally protected areas is calculated as a percentage of the total area of specially protected natural territories of the republic to the areas of areas where there are protected areas. The proportion of forest area for which a long-term forestry management plan has been developed: No calculation or formula is provided for the proportion of forest area for which a long-term forestry management plan has been developed. At the same time, it can be noted that the accounting and the share of areas is based on forest management materials according to the accounting of the forest fund.
Comments and restrictions:	To achieve this indicator, it is necessary to follow Chapter 12 and Article 51-1 of the Forest Code of the Republic of Kazakhstan dated July 8, 2003 and articles 20.23 of the Law of the Republic of Kazakhstan "on specially Protected Natural territories" and other regulatory legal acts arising from legislation in the field of forestry and specially protected natural territories.
6. Data availability and disaggregation	
Data availability and gaps:	General information is available on the websites of the Ministry of Ecology and Natural Resources of the Republic of Kazakhstan and its departments and subordinate institutions.
The level of disaggregation:	The data is disaggregated by categories of land, land and the specifics of its limitations established by legislation in the field of forestry and specially protected natural areas.

7. Comparability with international data/standards	Discrepancies may exist between the indicator data among countries presented internationally, since the area of the territory covered by forest is different for each country.
